Tim@X

In this topic we are interested in finding out approximate values of a number

Any number has digits along or before decimal and after decimal. The rightmost place is known as least significant place and leftmost place is most significant place

Most significant digit Least significant digit

e.g. M.S.D. LSD
 $(1) 5.7 \cdot 1 3 \oplus$

integer part
decimal part
→ floating point no.

The number of digits essentially required to represent a real no. ignoring exponent of base i.e. to write a number is known as number of significant digits in a real number.

$M \times 10^{\text{Exponent}}$; M: Mantissa

$$2.3 \rightarrow 2.3 \times 10^1$$

$$= 0.23 \times 10^2$$

$$= 0.0023 \times 10^3$$

in all cases 2 significant digits.

Q. The number of significant digits in the following numbers are :

1) 0.0005603000

2) 23.00006

3) $0.02.11006000$

$$\Rightarrow 0.0005603000 = 0.5603 \times 10^{-3}$$

∴ 4 significant digits.

$23.00006 \leftarrow 7$ significant digits

$0.02.11006000 \leftarrow 6$ significant digits

* If any number x is given and we want to approximate it by another number x_1 which has n -significant digits then two types of approximations are taken:

1. Truncation method.

In Truncation method, n -digits of the given numbers from left is taken and remaining are chopped off (विकृ छोटा)

$$\text{e.g. } x = 23.718928$$

that will be its truncated value of x if it is truncated by five significant digit?

$$\Rightarrow x_1 = 23.718 \leftarrow \text{Truncated value.}$$

2. Round-off method.

In this method of approximation up to n -significant places we take approximate value as 1^{st} n -places from left and remove the remaining portion.

(a) If removed portion is less than half of

place value at n^{th} place then the truncated value - is the round-off value. $\frac{1}{2} \times \text{place value of } n^{\text{th}} \text{ place}$

(b) If removed portion is greater than half

of its ^{place} value at n^{th} place then add one at the n^{th} ^{significant} place in the taken value

(c) If removed portion is equal to half of

its value at n^{th} place then its n^{th}

place in taken value has even digit.
(add nothing)

If n^{th} place in taken value has odd digit then add '1' at the n^{th} place

Round off the following digits upto 4th decimal significant digits

1) 41.1551002

2) 41.1549491

3) 41.155

4) 41.165

\Rightarrow	41.1551002	41.16
	41.1559491	41.15
	41.155	41.16
	41.165	41.16

$4^{\text{th}} \rightarrow$ significant place \Rightarrow place value. i) $\frac{1}{100} = 0.01$

half of the place value $= 0.005$

~~0.006~~

$\therefore 41.15 + 0.006 = 41.166$

~~41.15~~

① $0.0051002 > 0.005$

thus $41.15 + 0.01 = 41.16$

② $0.0049491 < 0.005$ thus do

nothing

~~41.15~~

③ $0.005 = 0.005 \left(= \frac{1}{2} \times 0.01 \right)$

& n^{th} place value odd thus ~~add 1~~ ^{add 1} ~~place value~~ ^{significat}

④ n^{th} significant value is even thus ~~add~~ add nothing.

Q. If the numbers given in 3-significant digits are 24.6, 2.46 and 0.246 and their sum will be reported as — ?

→ World of 3-significant digits -

24.6

2.46

0.246

27.306 World of 3-significant digits

By default no method is given for approximation then it is Round-off method

∴ Ans = 27.3

Error

If x is true value of number and if x_1 is approximate value of number then absolute error in approximation

$$\begin{aligned} E_A &= \text{True value} - \text{approximate value} \\ &= x - x_1 \end{aligned}$$

$$\text{Relative error : } E_R = \frac{E_A}{x}$$

$$\text{Percentage error : } E_p = E_R \times 100$$

Q. If 24.5 is approximated as 24 then what is absolute error in approximating?

What is relative error?

What is percentage error?

→ 0.5,

Q.

$$E_n = 0.5$$

$$E_p = \frac{0.5}{24.5}$$

$$E_p = \frac{0.5}{24.5} \times 100\%.$$

* If we have any function whose value is to be approximated at any point then in expansion of that function by taylor's theorem about any point we take upto certain terms which involves finite powers of x and remaining terms are truncated thus approximation of every function in Numerical analysis is a polynomial function.

Note

If we round off a number upto n -places after decimal then error in round-off has it's magnitude is,

$$| \text{Error}_{\text{round off}} | < \frac{1}{2} \times 10^{-n}$$

$$| \text{Round Error} | \leq \frac{1}{2} \times 10^{-n}$$

$$| \text{Error}_{\text{truncation}} | < 10^{-n}$$

Q. If we want to approximate the value of e^x at $x=1$ correctly upto two places after decimal then how many terms in taylor's expansion of e^x about $x=0$ will be taken?

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots + \frac{x^n}{n!} + \dots$$

1st n - terms

$$e^x = 1 + x + \frac{x^2}{2!} + \dots + \frac{x^{n-1}}{(n-1)!}$$

$$\left| \frac{x^n}{n!} \right| \leq \frac{1}{2} \times 10^{-2}$$

↑ युद्धेयम सबसे नवा term.

remainder after n-terms approximately

$$\text{ii. } \left| \frac{x^n}{n!} \right| \leq \frac{1}{2} \times 10^{-2} \leftarrow 9\text{-places off}$$

$$\text{at } x=1, \left| \frac{1}{n!} \right| \leq \frac{1}{200}$$

$$n! \geq 200$$

$$n=1, 1!$$

$$n=2, 2!$$

$$n=3, 3! = 6$$

$$n=4, 4! \approx 24$$

$$n=5, 5! = 120$$

$$n=6, 6! = 720$$

∴ leave term from $n=6$ onwards.

$$\therefore e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \frac{x^5}{5!}$$

$$x=1 \Rightarrow e^1 = 1 + 1 + \frac{1}{2!} + \frac{1}{3!} + \frac{1}{4!} + \frac{1}{5!}$$

$\frac{1}{2}$	0.5
$\frac{1}{3}$	$0.166 \Leftarrow 0.5/3$
$\frac{1}{4}$	$0.0415 \Leftarrow 0.166/4$
$\frac{1}{5}$	$0.0083 \Leftarrow 0.0415/5$
	2.7158

Q If we want to find approximate value of $\frac{1}{\sqrt{1+x}}$ for very very small value of x then which formula will be used for this purpose of approximation

$$\Rightarrow (1+x)^{-\frac{1}{2}} = 1 - \left(\frac{1}{2}\right)x + \frac{(-\frac{1}{2})(-\frac{1}{2}-1)}{2!}x^2 + \frac{(-\frac{1}{2})(-\frac{1}{2}-1)(-\frac{1}{2}-2)}{3!}x^3 + \dots$$

The best formula to approximate $\frac{1}{\sqrt{1+x}}$

$$\frac{1}{\sqrt{1+x}} = 1 - \frac{1}{2}x + \frac{3}{8}x^2 - \frac{5}{16}x^3 + \dots$$

Q If we want to find approximate value of $\sqrt{1+x}$ at $x = 1.9345678910112 \times 10^{-19}$ on a machine which takes no. of 15 digits then the formulae used for its accurate approx. is

(1) $\sqrt{1+x}$ itself

(2) $\frac{1+x}{\sqrt{1+x}}$

(3) $1 + \frac{1}{2}x - \frac{1}{3}x^2 + \dots$

(4) None

If we are approximating polynomial of degree n then remainder will be $(n+1)^{\text{th}}$ term.

PAGE NO.	Tim@X
DATE	/ /

Q. If e^x is approximate by Taylors expansion as polynomial function $\text{at } z = \frac{1}{2}$, then what must be degree of polynomial so that error in approximation does not exceed 10^{-2}

Let us assume that approximation is done by polynomial of order n then

$$\text{error} = \left| \frac{x^{n+1}}{(n+1)!} \right|_{x=\frac{1}{2}} \leq \frac{1}{100}$$

$$\frac{1}{(2^{n+1})(n+1)!} \leq \frac{1}{100}$$

$$n+1=4 \\ n=3 \Rightarrow \left| \frac{1}{2^{n+1}} e^{n+1} \right| \leq 100 \Rightarrow n \neq 14$$

~~$$\frac{1}{2^4 (4)!} \leq \frac{1}{100}$$~~

\therefore The degree of polynomial must be $n=3$.

Q. If we want to evaluate $\sqrt{1+x-1}$ at $x = 0.123456789 \times 10^{-8}$

then which formula will be taken to find it's approximate value with much accuracy?

\Rightarrow (1) $\sqrt{1+x-1}$

(2) $\frac{x}{\sqrt{1+x-1} + 1}$

(3) $\frac{x}{\sqrt{1+x-1}}$

(4) None

\Rightarrow As at very very small x
By Taylor's expansion.

$$\begin{aligned} \sqrt{1+x} - 1 &= (1+x)^{1/2} - 1 \\ &= 1 + \frac{1}{2}x + \frac{\left(\frac{1}{2}\right)\left(\frac{1}{2}-1\right)}{2!}x^2 + \frac{\left(\frac{1}{2}\right)\left(\frac{1}{2}-1\right)\left(\frac{1}{2}-2\right)}{3!}x^3 - \dots \\ &= \frac{1}{2}x - \frac{1}{8}x^2 + \frac{1}{16}x^3 \dots \end{aligned}$$

Approximation of functions :-

Whenever we are dealing with any non-polynomial functions then their values are approximated upto certain powers of x ; i.e. they are approximated by polynomial functions by using Taylor's th. & McLaurin's th. upto desired accuracy.

e.g. if e^x is approximated by poly. of degree 4 then its value at $\frac{1}{3}$ is - ?

solt:- $e^{-x} = 1 - x + \frac{x^2}{2!} - \frac{x^3}{3!} + \frac{x^4}{4!} + \dots$

$$\begin{aligned} \frac{1}{3} &= 0.3333 \\ \frac{1}{9} \times \left(\frac{1}{3}\right)^2 &= 0.3333^2 = 0.0555 \end{aligned}$$

$$= (1 + 0.0555 + 0.0005)$$

$$= (0.3333 + 0.0005)$$

$$= 1.0560$$

$$= 1.0560 - 0.3333$$

$$\frac{1}{12} \left(\frac{1}{3}\right)^3 = \frac{0.0555}{9} = 0.0061$$

$$\frac{1}{12} \left(\frac{1}{3}\right)^4 = \frac{0.0061}{12} = 0.0005$$

Numerical solution of algebraic and Transcendental equations.

In this topic we are interested in finding out approximate solution of $f(x) = 0$.

for this purpose several methods are used and in each method approximation made at n^{th} iteration will give some error

If ξ is the actual solution and x_n is its approximate solution then error in n^{th} approximation is denoted by E_n

$$E_n = \xi - x_n = \text{Error}$$

$$E_{n+1} = \xi - x_{n+1}$$

If $E_{n+1} = E_n^k (1 + \dots)$ i.e. $E_{n+1} \approx k E_n^k$

then order of error in approximation is k

$$\begin{aligned} \text{i.e. } E_{n+1} &= 10 E_n^2 + 7 E_n^3 + \dots \\ &\approx 10 E_n^2 \end{aligned}$$

The simplest and starting method to find approximate solution is Bisection method.

Bisection method: (Not in CSIR syllabus)

Pre-requisite: If $f(x)$ is continuous function in $[a, b]$ and if $f(a)$ and $f(b)$ are of opposite sign then \exists a root of $f(x)$ between a and b .

The first approximate root by bisection method of $f(x) = 0$ in $[a, b]$ is given by $x_1 = \frac{a+b}{2}$

Then the sign of $f(x)$ at x_1 is tested.
Now we apply the same procedure in
interval $[a, x_1]$ or $[x_1, b]$

We repeat this process to get successive
approximate value till it is desired.

Comment.

$(n+1)^{\text{th}}$ approximate value will lie in the
range, $x_{n+1} = \frac{1}{2^n} (b-a)$

so if number of iteration approaches
to infinity then length of interval in
which approximate solⁿ will lie equals
to '0' (approaches to 0)

$$x_{n+1} = \lim_{n \rightarrow \infty} \frac{1}{2^n} (b-a) \\ = 0$$

This method insures convergence of
approximate value to the root.

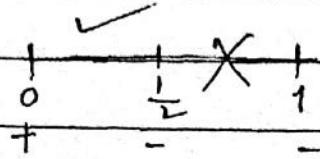

Q. find the 3rd approximate value of
equation $x^4 - 5x + 1 = 0$ lying betⁿ of 1.
Using Bisection method.

- ⇒
- 1) $f(x)$ is conti.
 - 2) $f(0) = 1, f(1) = -3$
 - 3) Both opposite sign so there lies a root
betⁿ of 1.

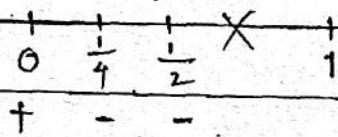

$$\therefore x_1 = \frac{0+1}{2} = \frac{1}{2}$$

	+	0	+	1/2	+	1
--	---	---	---	-----	---	---

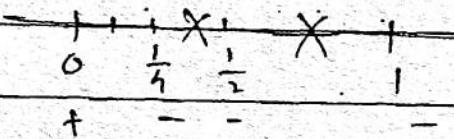

$$f\left(\frac{1}{2}\right) = \frac{1}{16} - \frac{5}{2} + 1 < 0$$

$$\therefore x_2 = \frac{0 + 1/2}{2} = \frac{1}{4}$$

$$f\left(\frac{1}{4}\right) = \frac{1}{256} - \frac{5}{4} + 1 < 0$$

$$x_3 = \frac{0 + 1/4}{2} = \frac{1}{8}$$

~~.....~~

Iteration Method. (In CSIR Syllabus)

If we want to find solution of $f(x) = 0$
then we re-write the given equation as
 $x = \phi(x)$

Hence solution of $f(x) = 0$ is same as
finding fixed point of $\phi(x)$.

In this procedure initial approximate solution
 $x_0 = 0$

and the 1st approximate solution is
obtained by putting initial approximate
 $x_1 = \phi(x_0)$

$$x_2 = \phi(x_1)$$

Hence by this procedure $(n+1)^{th}$ approximate
solution is

$$x_{n+1} = \phi(x_n), n=0,1,2,\dots$$

If $f(x) = 0$ is given then there is a lot
ways to find write $x = \phi(x)$

$$\text{e.g. } x^2 - x - 1 = 0$$

$$x = x^2 - 1$$

$$\text{or } x = (x+1)^{\frac{1}{2}}$$

$$\text{or } x - (x^2 - x - 1) = x$$

$$\text{or } x - \frac{x^2 - x - 1}{k} = x \quad k \neq 0 \quad \text{any constant}$$

for $x = x^2 - 1, x_0 = 2$

$$x_1 = 2^2 - 1 = 3$$

$$x_2 = 3^2 - 1 = 8$$

diverges to ∞ .

Theorem.

If $f(x) = 0$ is written as $x = \phi(x)$
where $\phi(x)$ and $\phi'(x)$ both are
continuous in an interval I containing
initial approximate value x_0 and
if $|\phi'(x)| < 1$ in that interval I
then $x = \phi(x)$ will converge to a
root of $f(x) = 0$.

Let ξ be the root of $f(x) = 0$ then

$$f(\xi) = 0$$

As $f(x) = 0$ is also $x = \phi(x)$

$$\therefore \xi = \phi(\xi)$$

$$x_{n+1} = \phi(x_n)$$

$$x_1 = \phi(x_0)$$

$$x_2 = \phi(x_1)$$

$$\xi - x_1 = \phi(\xi) - \phi(x_0)$$

$$\xi - x_2 = \phi(\xi) - \phi(x_1)$$

$$\vdots$$

$$\xi - x_{n+1} = \phi(\xi) - \phi(x_n)$$

ϕ is continuous, derivative exist

\therefore by Lagrange's thm

$$\xi - x_1 = \phi(\xi) - \phi(x_0) = (\xi - x_0) \phi'(\xi_1)$$

$$\xi - x_2 = \phi(\xi) - \phi(x_1) = (\xi - x_1) \phi'(\xi_2)$$

$$\vdots$$

$$(\xi - x_n) \phi'(\xi_{n+1})$$

Multiplying left with left & right with right

$$(e_i - x_{n+1}) = \cancel{(e_i - x_0)} \cdot (e_i - x_0) \phi'(x_1) \cdots \phi'(x_{n+1})$$

If $\phi'(x) \leq k < 1$

$$\begin{aligned} |e_i - x_{n+1}| &= |(e_i - x_0) \phi'(x_1) \cdots \phi'(x_{n+1})| \\ &\leq k^{n+1} |e_i - x_0| \end{aligned}$$

As limit $n \rightarrow \infty$, RHS $\rightarrow 0$ as $k < 1$.

$$\therefore \lim_{n \rightarrow \infty} |e_i - x_{n+1}| = 0$$

$$\therefore x_{n+1} = e_i$$

Note

$$e_i - x_{n+1} = \phi'(x_{n+1})(e_i - x_n)$$

$$e_{n+1} = k e_n$$

error of $(n+1)^{\text{th}}$ stage = $k \times$ error at n^{th} stage

So order of approximation

order of convergence of iteration

method is '1'.

Iterative method has linear convergence i.e. 1st order convergence

Q. If we want to find approximate solution of equation $x^3 - 3x + 1 = 0$. around $\frac{1}{3}$ then which of the following iterative formula will converge to the root?

$$1) x_{n+1} = \frac{x_n^3 + 1}{3}$$

$$2) x_{n+1} = x_n^3 - 2x_n + 1$$

$$3) x_{n+1} = (3x_n + 1)^{1/3}$$

$$4) x_{n+1} = \frac{1}{3 - x_n^2}$$

$$\Rightarrow \phi(x) = x^3 - 3x + 1$$

$$\phi'(x) = 3x^2 - 3$$

$$|\phi'(x)|_{\frac{1}{3}} = |3 \cdot \frac{1}{9} - 3| = |\frac{1}{3} - 3| > 1.$$

$\therefore 2^{\text{nd}}$ is not possible

$$\phi(x) = \frac{x^3 + 1}{3}$$

$$|\phi'(x)| = |x^2|_{\frac{1}{3}} = \frac{1}{9} < 1$$

$\therefore 1^{\text{st}}$ is possible.

$$\phi(x) = (3x - 1)^{1/3}$$

$$\phi'(x) = \frac{1}{3} (3x - 1)^{-2/3}$$

$$|\phi'(x)|_{\frac{1}{3}} = \frac{1}{3} \left(\frac{1}{(3 \cdot \frac{1}{3} - 1)^{2/3}} \right) > 1$$

$\therefore 3^{\text{rd}}$ position

$$\phi(x) = \frac{1}{3-x_0^2}$$

$$\phi'(x) = \frac{-2x_0}{(3-x_0^2)^2}$$

$$|\phi'(x)|_{x_0} = \left| \frac{-2/3}{(3-1/3)^2} \right| = \frac{2}{64} \leftarrow 1.$$

\therefore i) possible

If iterative formula in 1st option is used to find approximate value of the root then what is the 1st approximate and 2nd approximate value of the root?

$$x_0 = \frac{1}{3}$$

$$x_1 = \phi(x_0) = \frac{(1/3)^3 + 1}{3} = \frac{28}{27} \cancel{\times 3}$$

$$x_2 = \phi(x_1) = \frac{(28/27)^3 + 1}{3}$$

$$x^2 - x - 2 = 0$$

$$x_{n+1} = \sqrt{x_n + 2}$$

$$\phi(x) = \sqrt{x_n + 2}$$

$$|\phi'(x)|_1 = \left| \frac{1}{2\sqrt{x_n + 2}} \right| \leftarrow 1.$$

around $x=1$.

$$x_0 = 1 \left(+ \text{ve root} \right).$$

This iterative formula will converge to solution of $x^2 - 2x - 2 = 0$ equals 10

- 1) $\sqrt{2}$
- 2) -1
- 3) 2
- 4) $\sqrt{2 + \sqrt{2 + \sqrt{2 + \dots}}}$

→ Iterative formula $x_{n+1} = \sqrt{x_n + 1}$

$$\lim_{n \rightarrow \infty} x_n = l \quad \text{Suppose}$$

$$\lim_{n \rightarrow \infty} x_{n+1} = l$$

$$\therefore l^2 = l + 2$$

$$\therefore l^2 - l - 2 = 0$$

$$(l-2)(l+1) = 0$$

$$l = 2, -1$$

for 4th if $x = \sqrt{2+x}$

$$x^2 = 2+x$$

$$\Rightarrow x = 2, -1$$

Ans: (3), (4).

Newton-Raphson Method : (In CGIR syllabus)

This method is used to improve the approximate solution of $f(x) = 0$ obtained by any one of the methods available in the universe. →

→ like bisection etc.

If α is actual solution of $f(x) = 0$
then $f(\alpha) = 0$.

If x_n is approximate solution and $x_n + h$ is actual solution then $f(x_n + h) = 0$

$$\alpha = x_n + h$$

$$f(\alpha) = f(x_n + h) = 0$$

then by Taylor's series expansion

$$f(x_n + h) = f(x_n) + hf'(x_n) + \frac{h^2}{2!} f''(x_n) + \dots = 0$$

then

$$f(x_n + h) \approx f(x_n) + hf'(x_n)$$

By ignoring power of h from 2 onwards
we get as h is very small.

$$f(x_n) + hf'(x_n) \approx 0$$

$$\therefore h \approx -\frac{f(x_n)}{f'(x_n)}$$

$$\alpha_1 = x_n - \frac{f(x_n)}{f'(x_n)}$$

$$\therefore \boxed{x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}}$$

If we want to find solⁿ of $f(x) = 0$
Then N-R iterative formula is

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$$

$n = 0, 1, 2, \dots$

x_0 given

If ξ_1 is the actual root of $f(x) = 0$
then $f(\xi_1) = 0$

$$\Rightarrow f(x_n + (\xi_1 - x_n)) = 0$$

$$f(x_n) + (\xi_1 - x_n) f'(x_n) + \frac{(\xi_1 - x_n)^2}{2!} f''(x_n) + \dots = 0$$

$$\frac{-f(x_n)}{f'(x_n)} = (\xi_1 - x_n) + \frac{(\xi_1 - x_n)^2}{2!} \frac{f''(x_n)}{f'(x_n)} + \dots$$

$$x_n - \frac{f(x_n)}{f'(x_n)} = \xi_1 + \frac{(\xi_1 - x_n)^2}{2!} \frac{f''(x_n)}{f'(x_n)} + \dots$$

$$x_{n+1} - \xi_1 = \frac{(\xi_1 - x_n)^2}{2!} \frac{f''(x_n)}{f'(x_n)} + \dots$$

$$\epsilon_{n+1} = -\frac{f''(x_n)}{2f'(x_n)} \epsilon_n^2 (1 + \dots)$$

So order of convergence of newton Raphson method is '2'

Quadratic convergence or second order convergence

$f(x) = 0$

Q If we want the iterative formula to approximate positive square root or square root of a number N then the formula will be — ?

$\Rightarrow f(x) = 0$ to find solⁿ of

$$\text{let } x = N^{1/2}$$

$$x^2 = N$$

$$\therefore x^2 - N = 0$$

$$f(x) = 0$$

$$f(x) = x^2 - N$$

$$f'(x) = 2x$$

$$\frac{f''(x_n)}{f'(x_n)} + \dots = 0$$

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$$

$$= x_n - \frac{x_n^2 - N}{2x_n}$$

$$= \frac{2x_n^2 - x_n^2 + N}{2x_n}$$

$$= \frac{x_n^2 + N}{2x_n}$$

$$= \frac{1}{2} \left(x_n + \frac{N}{x_n} \right)$$

Q.

Consider the iterative formula ~~$x_{n+1} = 2x_n^2 + N$~~ the given formula is $3x_n^2$

Newton (1) Newton Raphson iterative formula to find cube root of N with 1st order convergence

② second (2) " — with 2nd order convergence
③ to find sq. root of N with 2nd order convergence

$$x_{n+1} = \frac{\frac{1}{3}x_n + \frac{1}{3}}{\frac{3x_n^2}{3x_n^2} + \frac{1}{3}} - \frac{x_n^3 - N}{3x_n^2}$$

$$\Rightarrow x_{n+1} - x_n = \frac{N - x_n^3}{3x_n^2} = - \left[\frac{x_n^2 - N}{3x_n^2} \right]$$

$$\Rightarrow f(x) = x^3 - N \quad \text{Now } f'(x) = 0 \Rightarrow x_n = N^{1/3}$$

DATE	1

Q.

If we want to find first and second approximate value of positive $\sqrt[3]{2}$ by Newton-Raphson method then initial approx value is 1.5 then x_1 and x_2 equals to

$$\Rightarrow x = \sqrt[3]{2}$$

$$x^2 = 2$$

By above

$$x_{n+1} = \frac{1}{2} \left(x_n + \frac{2}{x_n} \right)$$

$$x_1 = \frac{1}{2} \left(1.5 + \frac{2}{1.5} \right)$$

$$= \frac{17}{12}$$

$$x_2 = \frac{1}{2} \left(x_1 + \frac{2}{x_1} \right)$$

$$= \frac{1}{2} \left(\frac{17}{12} + \frac{24}{17} \right)$$

$$= + \frac{17^2 - 12 \times 24}{12 \times 17}$$

If we want to develop Newton Raphson formula for approximating sum of cube root & square root of any no N then $f(x) = ?$

Note: $x = N^{1/3} + N^{1/2} \Rightarrow (x - N^{1/2}) = N^{1/3}$

$\therefore 3x^2 \quad \text{Now } (x - N^{1/2})^3 = N$

$$\Rightarrow N = x^3 - 3x^2 N^{1/2} + 3xN - N^{3/2}$$

$$\Rightarrow N - x^3 - 3xN = -N^{1/2}(3x^2 + N)$$

$$\Rightarrow (N - x^3 - 3xN)^2 = N(3x^2 + N)$$

$$\Rightarrow f(x) = 0$$

Q. find first and second approximate value of $\sqrt[3]{7}$ by taking initial approximate value as 2.

$$\Rightarrow x = \sqrt[3]{7}$$

$$x^3 - 7 = 0$$

$$f(x) = x^3 - 7$$

$$f'(x) = 3x^2$$

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$$

$$= x_n - \frac{x_n^3 - 7}{3x_n^2}$$

$$= \frac{2x_n^3 + 7}{3x_n^2}$$

$$= \frac{2}{3}x_n + \frac{7}{3x_n^2}$$

$$= \frac{1}{3} \left[2x_n + \frac{7}{x_n^2} \right]$$

$$x_0 = 2$$

$$x_1 = \frac{1}{3} \left[1 + \frac{7}{4} \right] =$$

$$x_1 = \frac{23}{3}$$

$$x_2 = \frac{1}{3} \left[2 \times \frac{23}{3} + \frac{7 \times 9}{(23)^2} \right]$$

Solution of system of linear equations:

Here we have n -equations in n -unknowns

$$a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = b_1$$

$$a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n = b_2$$

$$\vdots$$

$$a_{nn}x_1 + a_{n2}x_2 + \dots + a_{nn}x_n = b_n$$

When coefficient matrix is non-singular
then system will have unique solution.

In Numerical analysis we have two
methods of finding solution.

i) Direct method (Exact solⁿ)

ii) Indirect / Iterative method (Approx solⁿ)

Direct method

a) Matrix inversion method ($Ax=B \Rightarrow x=A^{-1}B$)

b) Gauss elimination method

c) Gauss division method (Not in syllabus)

B) Gauss Elimination method:

In this method we form augmented
matrix $(A|B)$.

In the 1st step by using elementary
row transformation we make all the
elements in the 1st column below the
1st row equals to zero

In the 2nd step we make all the
elements in 2nd column below 2nd row
equal to zero using elementary row
transformation.

proceeding in similar fashion in the i^{th} step all we make all the elts below the i^{th} row equals to zero we go on doing this upto $(n-1)^{\text{th}}$ step
Thus principle part reduces to upper triangular matrix and from bottom to top we evaluate the value of one variable at one step and thus solution is achieved.

Note

If at the i^{th} step all the elements in i^{th} column except in the i^{th} row is made zero then the method will be known as Gauss Jordan method but this has to go upto n^{th} step and principle part becomes diagonal matrix and parallelly the value of each variable will be obtained in one step.

Q. Apply Gauss elimination method

$$x + y - z = 1$$

$$x - y + z = 1$$

$$-x + y + z = 1$$

to find solution of the following system of equation.

$$\Rightarrow \left[\begin{array}{ccc|cc} 1 & 1 & -1 & 1 \\ 1 & -1 & 1 & 1 \\ -1 & 1 & 1 & 1 \end{array} \right] \approx \left[\begin{array}{ccc|cc} 1 & 1 & -1 & 1 \\ 0 & -2 & 2 & 0 \\ 0 & 2 & 0 & 2 \end{array} \right]$$

$$\left[\begin{array}{ccc|cc} 1 & 1 & -1 & 1 \\ 0 & -2 & 2 & 0 \\ 0 & 0 & 2 & 2 \end{array} \right] \Rightarrow \begin{aligned} z &= 1 \\ -y + z &= 0 \Rightarrow y = 1 \\ x + y - z &= 1 \Rightarrow x = 1 \end{aligned}$$

Indirect / Iterative method.

If we have system of equation $Ax = B$ then we take A in such a way that all the diagonal entries of A are nonzero then from the 1st equation we write the value of x_1 in terms of remaining variables.

$$x_1 = \frac{b_1 - a_{12}x_2 - a_{13}x_3 - \dots - a_{1n}x_n}{a_{11}}$$

from 2nd eqn we write

$$x_2 = \frac{b_2 - a_{21}x_1 - a_{23}x_3 - \dots - a_{2n}x_n}{a_{22}}$$

proceeding in similar fashion the n th eqn writes x_n (n th variable)

$$x_n = \frac{b_n - a_{n1}x_1 - a_{n2}x_2 - \dots - a_{n-1}x_{n-1}}{a_{nn}}$$

In Jacobi's method (Not in syllabus)

\Leftrightarrow $(k+1)^{th}$ approximate value of each variable is obtained by putting k^{th} approximate value in the above system of eqn on RHS.

$$x_1^{k+1} = \frac{b_1}{a_{11}} - \frac{a_{12}}{a_{11}} x_2^k - \dots - \frac{a_{1n}}{a_{11}} x_n^k$$

$$x_n^{k+1} = \frac{b_n}{a_{nn}} - \frac{a_{n1}}{a_{nn}} x_1^k - \dots - \frac{a_{n-1}}{a_{nn}} x_{n-1}^k$$

In Gauss-Saidel method (In syllabus)

at each step of evaluation of the value of variables the latest evaluated value of variable on RHS are taken

$$x_1^{k+1} = \frac{b_1}{a_{11}} - \frac{a_{12}}{a_{11}} x_2^k - \dots - \frac{a_{1n}}{a_{11}} x_n^k$$

$$x_2^{k+1} = \frac{b_2}{a_{22}} - \frac{a_{21}}{a_{22}} x_1^{k+1} - \dots - \frac{a_{2n}}{a_{22}} x_n^{k+1}$$

$$x_n^{k+1} = \frac{b_n}{a_{nn}} - \frac{a_{n1}}{a_{nn}} x_1^{k+1} - \dots - \frac{a_{n-1}}{a_{nn}} x_{n-1}^{k+1}$$

Note

If 0^{th} or initial iterative value of variables are not given then they are taken as '0'.

Note:

The above methods converges to the actual solution if $\sum_{\substack{j=1 \\ j \neq i}}^n \left| \frac{a_{ij}}{a_{ii}} \right| \leq 1 \forall i$

and in atleast one case $\sum_{j=1}^n \left| \frac{a_{ij}}{a_{ii}} \right| < 1$

Q

Consider the system of equations

$$10x + y - 2z = 9$$

$$x + 10y + z = 17$$

$$x - 3y + 10z = 8$$

for this system of equation write down iterative formula to evaluate approximate value of x, y, z .

$$\Rightarrow x = \frac{9}{10} - \frac{1}{10}y + \frac{2}{10}z$$

$$x = 0.9 - 0.1y + 0.2z$$

$$y = 1.2 - 0.1x - 0.1z$$

$$z = 0.8 - 0.1x + 0.3y$$

$$x^{n+1} = 0.9 - 0.1y^n + \frac{2}{10}z^n$$

$$y^{n+1} = 1.2 - 0.1x^{n+1} - 0.1z^n$$

$$z^{n+1} = 0.8 - 0.1x^{n+1} + 0.3y^{n+1}$$

Q. find 1st and 2nd iterative value of x, y, z by Gauss Seidel method for the above eqns.

1st iterative value -

$$x^{(1)} = 0.9$$

$$\begin{aligned} y^1 &= 1.2 - (0.1)(0.9) \\ &= 1.11 \end{aligned}$$

$$\begin{aligned} z^1 &= (0.8) - (0.1)(0.9) + (0.3)(1.11) \\ &= 1.043 \end{aligned}$$

2nd iterative value of x

$$\begin{aligned} x &= (0.9) - (0.1)(1.11) + (0.2)(1.043) \\ &= 0.9976 \end{aligned}$$

$$\begin{aligned} y &= (1.2) - (0.1)(0.9976) + (0.1)(1.043) \\ &= 0.99594 \end{aligned}$$

$$\begin{aligned} z &= (0.8) - (0.1)(0.9976) + (0.3)(\\ &\approx 1 \end{aligned}$$

	x	y	z
1 st	0.9	1.11	1.043
2 nd	0.9976	0.99594	≈ 1

Q Consider the system of eqns given by

$$\begin{pmatrix} 0.99 & 1.01 \\ 1.01 & 0.99 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 2 \\ 2 \end{pmatrix}$$

If approximate value of solution is taken as

$\hat{x} = \begin{pmatrix} 2 \\ 0 \end{pmatrix}$ then find error and residue in computation.

\Rightarrow True value $x = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$

$$\text{Error } (E) = x - \hat{x}$$

$$= \begin{pmatrix} 1 \\ 1 \end{pmatrix} - \begin{pmatrix} 2 \\ 0 \end{pmatrix}$$

$$= \begin{pmatrix} -1 \\ 1 \end{pmatrix}$$

$$\text{Residue : } A(x - \hat{x}) = \begin{pmatrix} 0.99 & 1.01 \\ 1.01 & 0.99 \end{pmatrix} \begin{pmatrix} -1 \\ 1 \end{pmatrix}$$

$$= \begin{pmatrix} 0.02 \\ -0.02 \end{pmatrix}$$

$$= B - \hat{B}$$

$$= \begin{pmatrix} +1\% \\ -1\% \end{pmatrix} \quad \begin{matrix} 0.02 \text{ out of } 2 \\ -0.02 \text{ out of } 2 \end{matrix}$$

Comments

In the computation of x , Error is very very large but residue is very small.

Notes

There is no relationship b/w error and residue in approximation of solution of system of linear equation.

That means small error may result into larger or smaller residue or larger error may result into smaller or larger residue that all depends upon the coefficient.

Interpolation

If we are dealing with function of single variable then if we are given certain set of ordered pair of dependent or independent variable i.e. (x_i, y_i) also known as set of tabulated points.

If we have set of $(n+1)$ - tabulated points $(x_i, y_i), i=0, 1, \dots, n$, such that $x_0 < x_1 < x_2 < \dots < x_n$ then in this chapter we are interested in to fit a polynomial curve $y = f(x)$ which satisfy $y_i = f(x_i)$ which is further used to find approximate value of y for any x lying in the interval $[x_0, x_n]$. This process is known as interpolation and the fitted curve is known as interpolating curve. If this curve is used to find the value of y for x outside the interval then the process is known as extrapolation.

$$x \in (-\infty, x_0) \cup (x_n, \infty)$$

$$y = a_0 + a_1 x + \dots + a_n x^n$$

$$y_0 = a_0 + a_1 x_0 + \dots + a_n x_0^n$$

⋮

$$y_n = a_0 + a_1 x_n + \dots + a_n x_n^n$$

$$\begin{bmatrix} 1 & x_0 & \cdots & x_0^n \\ 1 & x_1 & & x_1^n \\ \vdots & \vdots & & \vdots \\ 1 & x_n & & x_n^n \end{bmatrix}$$

Van-der mode matrix.

Q

If we have $(n+1)$ -tabulated points then we can fit a polynomial of degree upto n .

n -tabulated points \leq poly. of degree $(n-1)$

5 -tabulated points ≤ 4 degree poly.

By direct method of finding interpolating curve assume $y = a_0 + a_1 x + \cdots + a_n x^n$ and on the RHS we put $x=x_i$ and on LHS we put $y=y_i$ to get $n+1$ linear equations in a_i 's which are also $n+1$ in number whose coefficient matrix is nonsingular (Because determinant of coefficient matrix is Van-der mode).

Hence unique value of a_i 's will be obtained
Thus interpolating curve will be obtained.

Another Direct Method.

Another direct method to find y is to write y as,

$$y = a_0 + a_1(x-x_0) + a_2(x-x_0)(x-x_1) + \\ a_3(x-x_0)(x-x_1)(x-x_2) + \dots \\ \dots + a_n(x-x_0)(x-x_1)(x-x_2)\dots(x-x_{n-1}).$$

$$\text{At } x=x_0, y=a_0$$

$$x=x_1, y=a_1$$

=
i

$$x=x_i, y=a_i$$

$$\vdots \\ x=x_n, y=a_n$$

Q. find the interpolating curve corresponding to the following table

x	0	1	2
y	1	0	-1

Method: (1)

points are $(0, 1), (1, 0), (2, -1)$

we can fit the curve of degree ≤ 2

Assume

$$y = a + bx + cx^2$$

$$(0, 1) \Rightarrow 1 = a$$

$$(1, 0) \Rightarrow 0 = a + b + c$$

$$(2, -1) \Rightarrow -1 = a + 2b + 4c$$

$$\begin{matrix} \text{for } a = 1, b + c = -1 \\ 2b + 4c = -2 \end{matrix} \quad \left\{ \Rightarrow c = 0 \Rightarrow b = -1 \right.$$

$$\therefore a = 1, b = -1, c = 0$$

$$\therefore y = a + bx + cx^2$$

$\therefore y = 1 - x$ is the required interpolating curve.

Method (2)

$$y = a + b(x-0) + c(x-0)(x-1)$$

$$\text{At } x=0, 1 = a$$

$$\text{At } x=1, 0 = 1 + b \Rightarrow b = -1$$

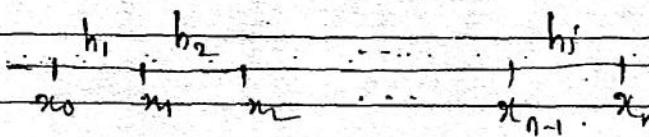

$$\text{At } x=2, \cancel{x(x-1)} \Rightarrow c = 0$$

$$\therefore \boxed{y = 1 - x}$$

Finite Difference

If we have set of $(n+1)$ - tabulated points where each successive points at finite difference then the distance between two successive points will be either constants or variable. or either in earlier case the set of points are known as evenly spaced and in the later case it is known as unevenly spaced points

$$\text{if } h_i = x_i - x_{i-1}$$

Evenly spaced set of points:

If we have set of tabulated points (x_i, y_i) then if $x_k - x_{k-1} = h \quad \forall k = 1, 2, \dots$ then h is known as Step length of tabulated points

$$\begin{array}{cccccc} x_0 & x_1 & x_2 & \dots & x_i \\ | & | & | & & | \\ x_0 & x_0 + h & x_0 + 2h & \dots & x_0 + ih \end{array}$$

$$\therefore x_i = x_0 + ih, \quad i = 0, 1, \dots, n$$

In these cases Newton sahab has introduced three operators to deal with the functional values of these tabulated points

- 1) Δ : Forward difference operator. (In Syllabus)
- 2) ∇ : Backward difference operator (In Syllabus)
- 3) δ : Central difference operator. (Not in Syllabus)

Forward difference operator of y_i :

$$\Delta y_i = y_{i+1} - y_i \quad x_i \quad x_{i+1}$$

Backward difference operator of $y_i = y_i - y_{i-1}$

$$\nabla y_i = y_i - y_{i-1}$$

Central difference operator of y_i :

$$f y_{i+\frac{1}{2}} = y_{i+1} - y_i$$

$$\Delta^2 y_i = \Delta(\Delta y_i)$$

$$= \Delta(y_{i+1} - y_i)$$

$$= y_{i+2} - y_{i+1} - (y_{i+1} - y_i)$$

$$= y_{i+2} - 2y_{i+1} + y_i$$

$$\nabla y_{i+1} = y_{i+1} - y_i$$

$$= \Delta y_i$$

$$\Delta^3 y_i = \Delta^2(\Delta y_i)$$

$$= \Delta^2(y_{i+1} - y_i)$$

$$= \Delta(\Delta y_{i+1} - \Delta y_i)$$

$$= \Delta(y_{i+3} - y_{i+2} - y_{i+1} - y_{i+1} + y_i)$$

$$= y_{i+3} - y_{i+2} - 2(y_{i+2} - y_{i+1}) + y_{i+1} - y_i$$

$$= y_{i+3} - 3y_{i+2} + 3y_{i+1} - y_i$$

$$= y_{i+3} - 3(y_{i+2} - y_{i+1}) - y_i$$

Shift operator (E)

$$E y_i = y_{i+1}$$

$$E^k y_i = y_{i+k}$$

Relation between E and Δ is that:

$$\Delta = E - 1$$

$$\Delta^k = (E - 1)^k$$

$$= E^k - kC_1 E^{k-1} + \dots + kC_{k-2} E^{k-2} + \dots + 1$$

$$\Delta y_i = y_{i+1} - y_i = (E - 1) y_i$$

Q. By using this concept obtain $\Delta^3 y_i$

$$\Rightarrow \Delta^3 y_i = (E - 1)^3 y_i$$

$$= (E^3 - 3E^2 + 3E - 1) y_i$$

$$= E^3 y_i - 3E^2 y_i + 3E y_i - y_i$$

$$= y_{i+3} - 3y_{i+2} + 3y_{i+1} - y_i$$

\equiv

If we have $(n+1)$ -tabulated points:

x	y	Δ	Δ^2	Δ^3	...
x_0	y_0	y_0			
x_1	y_1	y_1	y_0	y_0	
x_2	y_2	y_2	y_1	y_0	
x_3	y_3	y_3			
:	:	:	:	y_{n-2}	
x_{n-1}	y_{n-1}	y_{n-1}	y_{n-2}		
x_n	y_n				

Same table used for inverted ∇ operator:

x	y	∇	∇^2	∇^3	...
x_0	y_0	y_1			
x_1	y_1	y_2	y_2	y_3	
x_2	y_2	y_3	y_3	:	
x_3	y_3			y_n	
:	:	:	y_n		
x_n	y_n				

Q.

x	0	1	2	3
y	-1	2	-1	3

Convert given table into operator difference table.

x	y	Δ/∇	Δ^2/∇^2	Δ^3/∇^3
0	-1	3		
1	2	-3	-6	13
2	-1	4	7	
3	3			

Newton's Interpolation formulas:

For set of tabulated points $(x_i, y_i), i=0, 1, \dots, n$ which are evenly spaced,

$$x_k - x_{k-1} = h \quad : \text{Step length}$$

Let write

$$y(x) = a_0 + a_1(x - x_0) + a_2(x - x_0)(x - x_1) + \dots + a_n(x - x_0)(x - x_1) \dots (x - x_{n-1})$$

At $x = x_1$,

$$\frac{y_1 - y_0}{x_1 - x_0} = a_1$$

$$\frac{\Delta y_0}{h} = a_1$$

At $x = x_2$

$$\begin{aligned}
 y_2(x) &= y_0 + a_1(x_2 - x_0) + a_2(x_2 - x_0)(x_2 - x_1) \\
 &= y_0 + \frac{\Delta y_0}{h}(x_2 - x_0) + a_2(2h)(h) \\
 &= y_0 + \frac{\Delta y_0}{h}(2h) + a_2(2!)h^2 \\
 &= y_0 + 2\Delta y_0 + a_2(2!)h^2
 \end{aligned}$$

$$\therefore \frac{y_2 - 2(y_1 - y_0) + y_0}{h^2(2!)} = a_2$$

$$\therefore \frac{\Delta^2 y_0}{2! h^2} = a_2$$

$$\therefore \frac{\Delta^n y_0}{(n!) h^n} = a_n$$

$$\therefore y(x) = y_0 + \frac{\Delta y_0}{h} (x - x_0) + \frac{\Delta^2 y_0}{h^2(2!)} (x - x_0)(x - x_1) \\ + \dots + \frac{\Delta^n y_0}{h^n(n!)} (x - x_0)(x - x_1) \dots (x - x_{n-1})$$

$$\text{Let } x = x_0 + ph$$

$$x - x_0 = ph$$

$$x - x_0 - x_1 + x_1 = ph$$

$$x - x_1 + x_1 - x_0 = ph$$

$$x - x_1 + h = ph$$

$$x - x_1 = ph - h$$

$$x - x_1 = (p-1)h$$

$$\text{Similarly } x - x_2 = (p-2)h$$

:

$$x - x_i = (p-i)h$$

$$\therefore y(x) = y_0 + \frac{\Delta y_0}{h} ph + \frac{\Delta^2 y_0}{h^2(2!)} ph \times (p-1)h + \dots$$

$$\dots + \frac{\Delta^n y_0}{h^n(n!)} ph \times (p-1)h \times (p-2)h \times \dots \times (p-n+1)h$$

$$\therefore y(x) = y_0 + p \Delta y_0 + \frac{p(p-1)}{2!} \Delta^2 y_0 + \dots + \frac{p(p-1)\dots(p-n+1)}{n!} \Delta^n y_0.$$

This is known as Newton's forward difference interpolation formula.

$$x = x_0 + ph, \quad h: \text{step length}$$

x_0 is initial or starting value.

Now

$$\text{Let } y = a_0 + a_1(x - x_n) + a_2(x - x_n)(x - x_{n-1}) + \dots + a_n(x - x_n)(x - x_{n-1})\dots(x - x_1)$$

$$\text{At } x = x_n; \quad y_n = a_0$$

$$x = x_{n-1}; \quad y_{n-1} = y_n + a_1(-h)$$

$$a_1 = \frac{\nabla y_n}{h}$$

$$a_2 = \frac{\nabla^2 y_n}{h^2(2!)}$$

$$\therefore y = y_n + \frac{\nabla y_n}{h}(x - x_n) + \frac{\nabla^2 y_n}{h^2(2!)}(x - x_n)(x - x_{n-1}) + \dots + \frac{\nabla^n y_n}{h^n(n!)}(x - x_n)(x - x_{n-1})\dots(x - x_1)$$

$$x - x_n = ph$$

$$x - x_{n-1} = (p+1)h$$

:

$$x - x_{n-i} = (p+i)h$$

$$\therefore y = p \nabla y_n + \frac{p(p+1)}{2!} \nabla^2 y_n + \frac{p(p+1)(p+2)}{3!} \nabla^3 y_n + \dots + \frac{p(p+1)(p+2)\dots(p+(n-1))}{n!} \nabla^n y_n.$$

This is known as Newton's Backward interpolation.

Q. Consider set of points

x	0	1	2
y	-1	0	1

By Newton's forward and backward formula find interpolating curve

\Rightarrow	x	y	Δ/∇	Δ^2/∇^2
0	-1			
1	0	1		0
2	1			

Here $h = 1$, $x_0 = 0$, $x_n = 2$

By Newton's forward interpolation formula:

$$y = y_0 + p \Delta y_0 + \frac{p(p-1)}{2!} \Delta^2 y_0 + \dots + \frac{p(p-1) \dots p(n-1)}{n!} \Delta^n y_0$$

$$y = -1 + p(1) + \frac{p(p-1)}{2!} x_0$$

$$y = p-1 \quad \text{As } x = x_0 + ph$$

$$\therefore \boxed{y = x - 1} \quad \begin{aligned} p &= x - x_0 \\ p &= \cancel{x} \end{aligned}$$

By Newton's Backward interpolation formula,

$$y = y_n + p \nabla y_n + \frac{p(p+1)}{2!} \nabla^2 y_n + \dots$$

$$y = +1 + p(1) + 0$$

$$y = p+1$$

$$\text{As } x - x_n = ph$$

$$x - x_n = p$$

$$x - 2 = p$$

$$\therefore y = x - 2 + 1$$

$$\therefore \boxed{y = x - 1}$$

Comment.

If difference operators have upto k^{th} power equal to nonzero and rest highest powers are zero then it will interpolate curve of degree K .

Q. The set of data $(1, 2), (2, 5), (3, 10), (4, 17), (5, 26), (6, 37)$ will interpolate curve of degree upto — ?

x	y	Δ	Δ^2	Δ^3
1	2	3		
2	5	5	2	0
3	10	7	2	0
4	17	9	2	0
5	26	11	2	0
6	37			

$$\Delta^2 \neq 0, \Delta^3 = 4^3 = 0.$$

∴ By above comment, the given sets of data will interpolate a curve of degree upto 2.

$$y = 2 + p(3) + \frac{p(p-1)}{2} (2)$$

$$= 2 + 3p + p^2 - p$$

$$= 2 + 2p + p^2$$

$$= 2 + 2(x-1) + (x-1)^2$$

$$= 2 + 2x - 2 + x^2 - 2x + 1$$

$$y = x^2 + 1$$

$$x = x_0 + ph$$

$$x = t + p$$

$$p = x - 1$$

Lagrange's Interpolation Formulae :

If we have unevenly set of points
 $(x_i, y_i), i=0, 1, \dots, n$

$$y(x) = \frac{(x-x_0)(x-x_1) \dots (x-x_{n-1})}{(x_n-x_0)(x_n-x_1) \dots (x_n-x_{n-1})} y_n + \frac{(x-x_1)(x-x_2) \dots (x-x_n)}{(x_0-x_1)(x_0-x_2) \dots (x_0-x_n)} y_0 + \frac{(x-x_0)(x-x_2) \dots (x-x_n)}{(x_1-x_0)(x_1-x_2) \dots (x_1-x_n)} y_1 + \dots + \frac{(x-x_0)(x-x_1) \dots (x-x_{n-1})}{(x_n-x_0)(x_n-x_1) \dots (x_n-x_{n-1})} y_{n-1}$$

:

$$L_n(x) = \sum_{i=0}^n \frac{(x-x_0)(x-x_1) \dots (x-x_{i-1})(x-x_{i+1})}{(x_i-x_0)(x_i-x_1) \dots (x_i-x_{i-1})(x_i-x_{i+1}) \dots (x_i-x_{n-1})} y_i \\ = \sum_{i=1}^n l_i(x) y_i$$

This method is valid for set of tabulated points which is either evenly spaced or unevenly spaced.

$$1 \quad a_0 \quad a_1 \quad a_2 \quad \dots \quad a_n$$

$$y \quad a_0 \quad a_1 x \quad a_2 x^2 \dots \quad a_n x^n$$

$$y_0 \quad a_0 \quad a_1 x_0 \quad a_2 x_0^2 \dots \quad a_n x_0^n$$

:

$$y_n \quad a_0 \quad a_1 x_n \quad a_2 x_n^2 \dots \quad a_n x_n^n$$

eliminating 1, a_0, a_1, \dots, a_n from 1st, 2nd,

$(n+2)^{th}$ column we get -

$$\begin{vmatrix} 1 & x & \dots & x^n \\ y_0 & x_0 & x_0^2 & \dots \\ y_1 & x_1 & x_1^2 & \dots \\ \vdots & \vdots & \vdots & \vdots \\ y_n & x_n & x_n^2 & \dots \end{vmatrix} = 0$$

Vandermonde determinant.

Q. Consider set of points

x	0	1	2
y	-1	0	1

By Lagranges method find interpolating curve of the set of database.

$$\begin{aligned} \Rightarrow y &= \frac{(x-1)(x-2)}{(0-1)(0-2)} (-1) + \frac{(x-0)(x-2)}{(1-0)(1-2)} (0) \\ &\quad + \frac{(x-0)(x-1)}{(2-0)(2-1)} (1) \\ &= -\frac{(x-1)(x-2)}{2} + \frac{x(x-1)}{2} \\ &= (x-1) \left[\frac{x-x+2}{2} \right] \end{aligned}$$

$$y = x-1$$

Q. If we want to find the values at ??

x	1	2	3	4
y	7	11	??	19

Then we can use ...

- 1) Newton Raphson Interpolation formula.
- 2) Newton Forward Interpolation formula.
- 3) Lagranges Interpolation formula.
- 4) All.

\Rightarrow Given set of points are (1, 7), (2, 11), (4, 19) which are not evenly spaced

Therefore,

Newtons formulae invalid here

\therefore Only Lagranges interpolation formula is applicable.

\therefore Ans : (3).

Q.

x	1	2	2 1/2	3
y	7	11	??	19

Then we can use,

- 1) Newton Raphson formula.
- 2) Newton Forward Interpolation formula.
- 3) Lagrange's formula
- 4) All.

→ Here the points are evenly spaced

so Newton's formulae is applicable.

∴ All the methods are applicable.

Ans : (4) For SAQ.

: (1), (2), (3), (4) for JNTU.

Hermite Interpolation formula.

If we have set of tabulated points in which the value of independent variable alongwith corresponding value of the independent variable as well as with it's derivative, that means we should have $(n+1)$ points.

$(x_i, y_i, y'_i); i=0, 1, 2, \dots, n$.

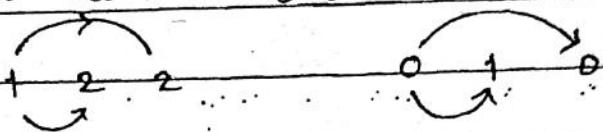

Then our goal is to fit polynomial of least degree which satisfy

$$H_{2n+1}(x_i) = y_i$$

$$H'_{2n+1}(x_i) = y'_i \quad i=0, 1, 2, \dots, n$$

then we can fit a polynomial of degree upto $(2n+1)$.

Q Consider set of tabulated points $(1, 2, 2)$ and $(0, 1, 0)$, find $H_3(x)$ which is
 \Rightarrow fitted over dataset
 \Rightarrow Let us assume $H_3(x) = a + bx + cx^2 + dx^3$

$$H_3(x) = a + bx + cx^2 + dx^3$$

$$H'_3(x) = b + 2cx + 3dx^2$$

$$\text{At } (1, 2, 2)$$

$$x_i \quad y_i \quad y'_i$$

$$2 = a + b + c + d \quad \text{--- (1)}$$

$$\text{At } (0, 1, 0)$$

$$x_i \quad y_i \quad y'_i$$

$$1 = a \quad \text{--- (2)}$$

$$\text{at } x_i = 1, y'_i = 2$$

$$\therefore 2 = b + 2c + 3d$$

$$\text{and at } x_i = 0, y'_i = 0$$

$$\therefore 0 = b \quad \text{--- (3)}$$

\therefore from (1), (2), (3)

$$2 = 1 + 0 + c + d$$

$$\therefore c + d = 1 \quad \text{--- (4)}$$

$$\text{Also } 2c + 3d = 2 \quad \text{--- (5)}$$

Solving (4) and (5) we get

$$-d = -1 \Rightarrow d = 1$$

$$\Rightarrow c = 0$$

$$\therefore H_3(x) = a + bx + cx^2 + dx^3$$

$$= 1 + x^3$$

Remark: For 'n' tabulated points degree of Hermite polynomial will be upto $2n-1$.

For $(n+1)$ -tabulated points degree will be upto $2n+1$.

Spline Interpolation.

In general fitting a curve for a whole interval resultant into much error in approximation at points in the interval. So it was decided to fit local curves in the interval $[x_0, x_n]$ where one curve will be for $[x_0, x_1]$ another curve will be for $[x_1, x_2]$ and i^{th} curve will be for $[x_{i-1}, x_i]$, n^{th} curve will be for $[x_{n-1}, x_n]$ and each of such curve should agree at their end points. The collection of all such curve is interpolating curve and in each subinterval the fitted curve are known as spline curves.

$$S(x) = \begin{cases} S_1(x) & ; x_0 \leq x \leq x_1 \\ S_2(x) & ; x_1 \leq x \leq x_2 \\ S_3(x) & ; x_2 \leq x \leq x_3 \\ \vdots & \vdots \\ S_i(x) & ; x_{i-1} \leq x \leq x_i \\ \vdots & \vdots \\ S_n(x) & ; x_{n-1} \leq x \leq x_n \end{cases}$$

There are lot of spline curves are available simplest one is linear spline curve, another one is quadratic spline curve, cubic spline curve etc...

If we are fitting n^{th} degree spline curves then to fit the curve we use $S(x), S'(x), S''(x), \dots, S^{n-1}(x)$ as continue in $[x_0, x_n]$.

Q. Consider the set of points $(1, 2), (2, 5), (4, 7)$
By using linear spline find value of y at 3
and also value of y at 1.5 .

$$\text{Spline function } S(x) = \begin{cases} 3x - 1 & ; 1 \leq x \leq 2 \\ x + 3 & ; 2 \leq x \leq 4 \end{cases}$$

$$y - y_1 = m(x - x_1)$$

$$y - 2 = m(x - 1)$$

$$y - 2 = 3x - 3 \quad \text{Also} \quad y - 5 = (x - 2)$$

$$y = 3x - 1$$

$$m = \frac{y_2 - y_1}{x_2 - x_1} = 3$$

$$y = x + 3$$

$$\therefore y : 3 \in [2, 4]$$

$$\therefore y(\text{at } 3) = 3 + 3 = 6$$

$$\text{and } 1.5 \in [1, 2]$$

$$\therefore y(\text{at } 1.5) = 3(1.5) - 1$$

$$= 3.5$$

Q. Consider set of points $(1, 0), (2, 1)$ & $(4, -1)$
By using quadratic spline interpolation formula find $y(3)$ and $y(1.5)$

\Rightarrow Let

$$S(x) = \begin{cases} ax + bx^2 + cx^3 & ; 1 \leq x \leq 2 \\ dx + ex^2 + fx^3 & ; 2 \leq x \leq 4 \end{cases}$$

$$\text{At } x=1, y=0$$

$$\therefore 0 = a + b + c \quad \text{--- (1)}$$

$$\text{At } x=2, y=1$$

$$1 = a + 2b + 4c \quad \text{--- (2)} \quad 1 = d + 2e + 4f \quad \text{--- (3)}$$

$$\text{At } x=4, y=-1$$

$$-1 = d + 4e + 16f \quad \text{--- (4)}$$

Also

$$s'(x) = \begin{cases} b+2cx & 1 \leq x \leq 2 \\ e+2fx & 2 \leq x \leq 4 \end{cases}$$

Left hand derivative at $x=2$ must be equal to Right hand derivative at $x=4$ because s and s' should be continuous

$$\therefore b+4c = e+4f \quad \textcircled{5}$$

Also from $s(x)$

$$\text{RHL} = \text{LHL} \text{ by continuity}$$

$$\therefore a+2b+4c = d+2e+4f \quad \textcircled{6}$$

Solving equation $\textcircled{1}$ to $\textcircled{6}$ we get

- Numerical Differentiation -

If we have set of tabulated points (x_i, y_i)
 $i=0, 1, 2, \dots, n$ then by Newton forward
interpolation formula for evenly spaced set
of points :

NFDI :

$$y = y_0 + p \Delta y_0 + \frac{p(p-1)}{2!} \Delta^2 y_0 + \dots \quad x = x_0 + ph.$$

NBDI :

$$y = y_0 + p \nabla y_0 + \frac{p(p+1)}{2!} \nabla^2 y_0 + \dots \quad x = x_0 + ph.$$

In Numerical analysis we are interested in
approximate finding out $(dy/dx)|_{x=x_0}$ and
 $(dy/dx)|_{x=x_n}$.

$$\text{As } \frac{dy}{dx} = \frac{dy}{dp} \cdot \frac{dp}{dx}$$

$$\text{as } x = x_0 + ph$$

$$dx = h dp \therefore dp/dx = 1/h$$

$$\therefore \frac{dy}{dx} = \frac{1}{h} \frac{dy}{dp}$$

$$= \frac{1}{h} \left\{ \Delta y_0 + \frac{2p-1}{2!} \Delta^2 y_0 + \dots \right\}$$

$$\text{At } x = x_0 \Rightarrow p = 0$$

$$\therefore \left(\frac{dy}{dx} \right)_{x=x_0} = \frac{1}{h} \left(\frac{dy}{dp} \right)_{p=0}$$

$$= \frac{1}{h} \left\{ \Delta y_0 - \frac{1}{2!} \Delta^2 y_0 + \frac{1}{3} \Delta^3 y_0 - \frac{1}{4} \Delta^4 y_0 + \dots \right\}$$

$$\left(\frac{dy}{dx} \right)_{x=x_n} = \frac{1}{h} \left(\frac{dy}{dp} \right)_{p=0}$$

$$= \frac{1}{h} \left\{ \nabla y_n + \frac{1}{2} \nabla^2 y_n + \frac{1}{3} \nabla^3 y_n + \dots \right\}$$

Q. If in a company production of football in Lakhs years observed as follows:

Years	Production
2010	5
2011	10
2012	8
2013	7
2014	9

What is the annual rate of production of football in year 2010 and year 2014 approximated by the given data.

x	y	Δ/∇	Δ^2/∇^2	Δ^3/∇^3	Δ^4/∇^4
2010	5				
2011	10	5	-7	8	-6
2012	8	-2	1	4	
2013	7	-1	3		
2014	9	2			

$$\left(\frac{dy}{dx} \right)_{x=2010} = \frac{1}{h} \left\{ \Delta y_0 - \frac{1}{2} \Delta^2 y_0 + \frac{1}{3} \Delta^3 y_0 - \frac{1}{4} \Delta^4 y_0 \right\}$$

$$= \frac{1}{1} \left\{ 5 - \frac{1}{2} (-7) + \frac{1}{3} (8) - \frac{1}{4} (-6) \right\}$$

$$= \frac{38}{3}$$

$$\left(\frac{dy}{dx} \right)_{x=2014} = \frac{1}{h} \left(\nabla y_n + \frac{1}{2} \nabla^2 y_n + \frac{1}{3} \nabla^3 y_n + \frac{1}{4} \nabla^4 y_n \right)$$

$$= 2 + \frac{1}{2} (3) + \frac{1}{3} (2) + \frac{1}{4} (-6)$$

$$= \frac{8}{3}$$

Lakhs

Negative \Rightarrow Negative rate of growth.
+ve value \Rightarrow Positive rate of growth.

If we want to find approximate value of $f'(x_0)$ then if we have data available at one step ahead of x_0 and one step before x_0 then it may be approximated by

$$\frac{f(x_0+h) - f(x_0-h)}{2h} \approx f'(x_0)$$

$$\lim_{h \rightarrow 0} \frac{f(x_0+h) - f(x_0-h)}{2h} = \frac{0}{0} \text{ form}$$

$$\lim_{h \rightarrow 0} \frac{f'(x_0+h) + f'(x_0-h)}{h}$$

Also for 2-step ahead \rightarrow 2 step before

$$f'(x_0) \approx \frac{f(x_0+2h) - f(x_0-2h)}{4h}$$

Q. If we approximate $f'(x)$ by above formula then error in approximation is of order — and error in approximation is approximately —

$$f'(x) \approx \frac{f(x+h) - f(x-h)}{2h}$$

Now,

$$f(x_0+h) = f(x_0) + h f'(x_0) + \frac{h^2}{2!} f''(x_0) + \dots$$

$$f(x_0-h) = f(x_0) - h f'(x_0) + \frac{h^2}{2!} f''(x_0) - \dots$$

$$\begin{aligned} \frac{f(x_0+h) - f(x_0-h)}{2h} &= \frac{2h f'(x_0) + 2(h^3/3!) f'''(x_0)}{2h} + \dots \\ &= f'(x_0) + \frac{h^2}{3!} f'''(x_0) + \dots \end{aligned}$$

Error in approximations

$$E = f'(x_0) - \left(\frac{f(x_0+h) - f(x_0-h)}{2h} \right)$$

$$= -\frac{h^2}{6} f'''(x_0)$$

∴ order of error is order of h^2 i.e. = 2.

Error is ~~$\approx -\frac{h^2}{6} f'''(x_0)$~~ .

$$f(x_0) = f_0$$

$$f(x_0-h) = f_{-1}$$

$$f(x_0+h) = f_1$$

$$f(x_0+ih) = f_i$$

Numerical Integration -

If we have set of tabulated points.
 $(x_i, y_i), i=0, 1, \dots, n$ then we can fit a curve of degree upto n .

$$y(x) = y_0 + \frac{P \Delta y_0}{2!} + \frac{P(P-1)}{3!} \Delta^2 y_0 + \dots + \frac{P(P-1) \dots (P-(n-1))}{n!} \Delta^n y_0$$

On the basis of given set of tabulated pts
we are interested in finding out $\int_{x_0}^{x_n} y dx$

$$\text{Ans: } \int_{x_0}^{x_n} y dx = \int_{x_0}^{x_1} y dx + \int_{x_1}^{x_2} y dx + \dots + \int_{x_{n-1}}^{x_n} y dx$$

We are interested in finding out approximate value of integral. We divide integral into sum of integrals where each subintegral takes fixed number of tabulated points and then over tabulated points of sub-interval we fit local curve of suitable degree in each of them and we evaluate approximate value of the integral by this process.

1) Trapezoidal rule of approximation:

It consists of two tabulated points in each of the subinterval over which integration is approximated.

$$x = x_0 + ph$$

$$dx = h dp$$

$$\int_{x_0}^{x_n} y \, dx = \int_{x_0}^{x_1} y \, dx + \int_{x_1}^{x_2} y \, dx + \dots + \int_{x_{n-1}}^{x_n} y \, dx$$

In interval $[x_0, x_1]$	x	y	Δ
	x_0	y_0	y_0
	x_1	y_1	

$$y(x) = y_0 + p(y_1 - y_0)$$

$$\int_{x_0}^{x_1} y \, dx = h \int_{x_0}^{x_1} (y_0 + p(y_1 - y_0)) \, dp$$

$$\approx h \int_0^1 [y_0 + p(y_1 - y_0)] \, dp$$

$$\approx h \left[y_0 + \frac{p^2}{2} (y_1 - y_0) \Big|_0^1 \right]$$

$$\approx h \left[y_0 + \frac{1}{2} (y_1 - y_0) \right]$$

$$\approx \frac{h}{2} [y_0 + y_1]$$

$$\text{Similarly, } \int_{x_1}^{x_2} y \, dx \approx \frac{h}{2} [y_1 + y_2]$$

$$\int_{x_{n-1}}^{x_n} y \, dx \approx \frac{h}{2} [y_{n-1} + y_n]$$

Adding all these n -integrals we get,

$$\int_{x_0}^{x_n} y \, dx = \frac{h}{2} (y_0 + y_1) + \frac{h}{2} (y_1 + y_2) + \dots + \frac{h}{2} (y_{n-1} + y_n)$$

$$= \frac{h}{2} \{ (y_0 + y_n) + 2(y_1 + y_2 + \dots + y_{n-1}) \}$$

OR

$$\int_{x_0}^{x_n} y dx = h \left\{ \frac{1}{2} (y_0 + y_n) + (y_1 + y_2 + \dots + y_{n-1}) \right\}$$

= distance betⁿ two consecutive ordinates

$\times \{ \text{mean of 1st and last ordinates} + \text{sum of all intermediate ordinates} \}$

This rule is known as Trapezoidal rule.

Now

$$\int_{x_0}^{x_1} y dx = \int_{x_0}^{x_1} (y_0 + hy'_0 + \frac{h^2}{2!} y''_0 + \dots) dx$$

(y about $x=x_0$)

∴

$$y = y_0 + (x - x_0) y'_0 + \frac{(x - x_0)^2}{2!} y''_0 + \dots$$

$$\therefore \int_{x_0}^{x_1} [y_0 + (x - x_0) y'_0 + \frac{(x - x_0)^2}{2!} y''_0 + \dots] dx$$

$$= h y_0 + \frac{h^2 y'_0}{2!} + \frac{h^3}{6} y''_0 + \dots$$

∴ Actual value of integration:

$$\int_{x_0}^{x_1} y dx = h y_0 + \frac{h^2}{2!} y''_0 + \frac{h^3}{8} y'''_0 + \dots$$

Approximate value of integration is

$$\int_{x_0}^{x_1} y dx = \frac{h}{2} (y_0 + y_1)$$

$$= \frac{h}{2} \left\{ y_0 + (y_0 + h y'_0 + \frac{h^2}{2!} y''_0 + \frac{h^3}{3!} y'''_0 + \dots) \right\}$$

$$= \frac{h}{2} \left\{ 2 y_0 + h y'_0 + \frac{h^2}{2!} y''_0 + \frac{h^3}{3!} y'''_0 + \dots \right\}$$

$$= h y_0 + \frac{h^2}{2!} y'_0 + \frac{h^3}{4} y''_0 + \frac{h^4}{2 \cdot 3!} y'''_0 + \dots$$

Therefore

$$\text{Error} = \text{Actual value} - \text{Approximate value}$$

$$= \left[\int_{x_0}^{x_1} y \, dx \right]_{\text{Act}} - \left[\int_{x_0}^{x_1} y \, dx \right]_{\text{Approx}}$$

$$= hy_0 + \frac{h^2}{2!} y'_0 + \frac{h^3}{6} y''_0 + \frac{h^4}{24} y'''_0 + \dots$$

$$- \left\{ hy_0 + \frac{h^2}{2!} y'_0 + \frac{h^3}{6} y''_0 + \frac{h^4}{24} y'''_0 + \dots \right\}$$

$$= h^3 \left(\frac{1}{6} - \frac{1}{4} \right) y''_0 + h^4 \left(\frac{1}{24} - \frac{1}{12} \right) y'''_0 + \dots$$

$$= -\frac{h^3}{12} y''_0 - \frac{h^4}{24} y'''_0 + \dots$$

$$\therefore \{\text{Error}\}_{[x_0, x_1]} = -\frac{h^3}{12} y''_0$$

\therefore Error in the whole interval $[x_0, x_n]$ is

$$\{\text{Error}\}_{[x_0, x_n]} = -\frac{h^3}{12} \{y''_0 + y''_1 + y''_2 + \dots + y''_{n-1}\}$$

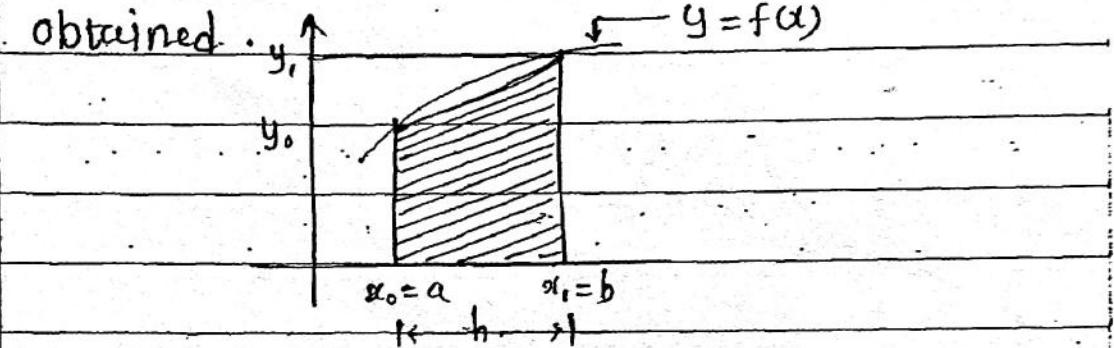

$$< n \times \left(-\frac{h^3}{12} y''_{\max} \right)$$

$$\text{As } nh = b-a = (x_n - x_0)$$

$$\text{Error} \approx -\frac{(b-a)}{12} h^2 y''_{\max}$$

This is error in approximation in the trapezoidal rule of order 2

Q. The geometrical significance of this rule is that the curve $y = f(x)$ is replaced by n straight lines joining the points (x_0, y_0) and (x_1, y_1) and $(x_2, y_2) \dots (x_{n-1}, y_{n-1})$ and (x_n, y_n) . The area bounded by the curve $y = f(x)$, the ordinates $x = x_0$ and $x = x_n$ and the x -axis is then approximately equivalent to the sum of the areas of n Trapeziums obtained.

$$\text{Shaded Area} = \text{Area of Trapezium} \approx \frac{1}{2} [f(a) + f(b)]h$$

Q. If we want to find the approximate value of $\int x^2 dx$ by using trapezoidal rule and taking step length of $1/3$ then its approximate value will be — ?

Also find error in approximation.

x	0	$1/3$	$2/3$	$3/3 = 1$
$y = x^2$	0	$1/9$	$4/9$	1

$$\int_0^1 x^2 dx \approx \frac{1/3}{2} \left\{ (0+1) + 2 \left(\frac{1}{9} + \frac{4}{9} \right) \right\}$$

$$\approx \frac{19}{54}$$

$$\begin{aligned}\text{Error} &= x_T - x_A \\ &= \frac{1}{3} - \frac{19}{54} \\ &= \frac{18 - 19}{54}\end{aligned}$$

$$\text{Error} = \frac{-1}{54}$$

$$\begin{aligned}\text{Relative error} &= \frac{\text{Error}}{\text{True value}} \quad \left| \int x^2 dx = \frac{x^3}{3} \right| \\ &= \frac{-1/54}{1/3} \\ &= -\frac{1}{18}\end{aligned}$$

$$\begin{aligned}\text{Percentage error} &= (\text{Relative error}) \times 100 \\ &= -\frac{1}{18} \times 100 \\ &= -\frac{100}{18} \%\end{aligned}$$

Note:

- 1) In Trapezoidal rule we fit linear curve in each subinterval so if the actual curve is also linear then trapezoidal rule will give no error in approximation of integral over those curves.
- 2) If by Trapezoidal rule we find approximate integral of a curve in interval $[x_0, x_n]$ in which curve is convex then approximate value of the integral will be greater than true value of the integral.

Q. If we approximate $\int_0^1 x^4 dx$ by trapezoidal rule of steplength 0.01 then approximate value of the integral will be — ?

- 1) $1/5$ 2) $> 1/5$ 3) $< 1/5$ 4) None

$$f(x) = x^4$$

$$f''(x) = 12x^2 > 0 \text{ in } (0,1)$$

$\therefore f(x)$ is convex in $(0,1)$

\therefore Approx. Value $>$ True Value

$$\therefore \text{Approx. Value} > \frac{1}{5}$$

Ans : (2) ~~1/5~~

Q. If we want to find approximate value of integral $\int_0^1 (3x+7) dx$ by trapezoidal rule of the steplength 0.0001 then its value will be — ?

- 1) $3/2$ 2) 7 3) $17/2$ 4) None

\Rightarrow By Note (1) above,

The given curve is linear then the Trapezoidal rule will give no error.

\therefore Approx Value = Actual Value

$$= \frac{17}{2}$$

\therefore Ans = (3) ~~17/2~~

2) Midpoint Approximation.

If we have set of tabulated points (x_i, y_i)
 $i=0, 1, \dots, n$ then $\int y dx$ is approximated in
each subinterval $[x_{i-1}, x_i]$ by the functional value
at the midpoint

$$\int_{x_0}^{x_n} y dx \approx \sum_{i=0}^n h f(m_i) \text{ where for } [x_{i-1}, x_i] \\ m_i = \frac{x_i + x_{i-1}}{2}$$

Q.

Error in Approximation:

$$X = \int_{x_0}^{x_n} y dx = \int_{x_0}^{x_n} y_0 + (x - x_0) y'_0 + \frac{(x - x_0)^2}{2!} y''_0 + \dots$$

$$X_{\text{approx}} = h f\left(\frac{x_0 + x_1}{2}\right) \quad \begin{array}{c} \leftarrow h \rightarrow \\ x_0 \quad \frac{x_0 + x_1}{2} \quad x_1 \end{array}$$

$$= h f\left(x_0 + \frac{h}{2}\right)$$

$$= h \left\{ y_0 + \frac{h}{2} y'_0 + \frac{(h/2)^2}{2!} y''_0 + \dots \right\}$$

$$X_{\text{True}} = h y_0 + \frac{h^2}{2} y'_0 + \frac{h^3}{6} y''_0 + \frac{h^4}{24} y'''_0 + \dots$$

$$\text{Error (E)} = X_{\text{True}} - X_{\text{approx}}$$

3)

$$= h^3 \left(\frac{1}{6} - \frac{1}{8} \right) y''_0 + \dots$$

$$= \frac{h^3}{24} y''_0 + \dots$$

$$\therefore \text{Error in } [x_0, x_1] = \frac{h^3}{24} y''_0$$

\therefore Total error,

$$E = \frac{h^3}{24} [y''_0 + y''_1 + y''_2 + \dots + y''_{n-1}]$$

$$|E_{[a,b]}| \leq \frac{h^3}{24} |f''(x)|_{\max}$$

$$\leq \frac{(b-a)}{12} h^2 |f''(x)|_{\max}.$$

Q. If $\int_a^b f(x) dx$ is approximated by $\sum_{i=1}^n f(m_i) \cdot h$, where m_i is the midpoint of i^{th} subinterval in partition of $[a,b]$ in partition of $[0,1]$, then modulus or magnitude of error in approximation is bounded by _____?

$$\Rightarrow \int_a^b f(x) dx \approx \sum_{i=1}^n f(m_i) \cdot h$$

$$|E| \leq \frac{(b-a)}{24} h^2 |f''(x)|_{\max}$$

$$\leq \frac{h^2}{24} |f''(x)|_{\max} \text{ on } [0,1]$$

3) Simpson's $(1/3)^{\text{rd}}$ Rule:

If in approximation of integration we take three tabulated points in each subintegral then this process of approximation results into Simpson's $(1/3)^{\text{rd}}$ rule.

$$\int_a^{x_n} y dx = \int_a^{x_1} y dx + \int_{x_1}^{x_2} y dx + \dots + \int_{x_{n-2}}^{x_n} y dx \quad (1)$$

In $[x_0, x_2]$

$$\int_{x_0}^{x_2} y dx \approx h \int_0^2 \left(y_0 + p \Delta y_0 + \frac{p(p-1)}{2!} \Delta^2 y_0 \right) dp$$

$$\approx h \left[2y_0 + \frac{p^2}{2} \Delta y_0 \right] + \dots$$

$$\approx h \left[2y_0 + 2 \Delta y_0 + \frac{(8/3 - 2)}{2!} \Delta^2 y_0 \right]$$

$$\approx h [2y_0 + 2(y_1 - y_0) + (1/3)(y_2 - 2y_1 + y_0)]$$

$$\approx \frac{h}{3} [y_0 + 4y_1 + y_2]$$

eqn (1) becomes

$$\int_{x_0}^{x_n} y dx = \frac{h}{3} (y_0 + 4y_1 + y_2) + \frac{h}{3} (y_2 + 4y_3 + y_4)$$

$$+ \dots + \frac{h}{3} (y_{n-2} + 4y_{n-1} + y_n)$$

$$= \frac{h}{3} [y_0 + 4(y_1 + y_3 + \dots + y_{n-1})]$$

$$+ 2(y_2 + y_4 + \dots + y_{n-2}) + y_n]$$

Note:

Simpsons $(1/3)^{\text{rd}}$ rule will be applicable over sets of data which are multiple of three , multiple of $2+1, \dots$

$$\int_{x_0}^{x_n} y dx = 3 + 2 + 2 + \dots$$

$$\text{Multiple of } 2 + 1 = M(2) + 1$$

Q. By taking steplength $1/4$, find the approximate value of $\int_0^1 x^2 dx$ by simpsons $(1/3)$ rd rule also find an error.

\Rightarrow	x	0	$1/4$	$2/4$	$3/4$	$4/4 = 1$
	Y	0	$1/16$	$1/4$	$9/16$	1

↑ ↑ ↓
 Once Twice Three

$$\int_0^1 x^2 dx \approx \frac{1}{12} [(0+1) + 2\left(\frac{1}{16}\right) + 4\left(\frac{1}{16} + \frac{9}{16}\right)]$$

$$\approx \frac{1}{3}$$

As simpsons $(1/3)$ rd rule takes three tabulated points in each subintegral so if the actual curve is quadratic then approximate value and true value of the integral will coincide.

Q. By simpsons $(1/3)$ rd rule the approximate value of $\int_0^1 (5x^2 + 6x + 7) dx$ by taking steplength of $1/50$ will be

- 1) $5/3$
- 2) 3
- 3) 7
- 4) $95/3$

$$\Rightarrow \int_0^1 (5x^2 + 6x + 7) dx = \frac{5}{3} + 3 + 7$$

$$= \frac{35}{3}$$

Actual value of $\int_{x_0}^{x_2} y \, dx$

$$= \int_{x_0}^{x_2} \left(y_0 + (x - x_0) y'_0 + \frac{(x - x_0)^2}{2!} y''_0 + \frac{(x - x_0)^3}{3!} y'''_0 \right. \\ \left. + \frac{(x - x_0)^4}{4!} y^{\text{iv}}_0 + \dots \right) dx$$

$$= 2hy_0 + \frac{(2h)^2}{2!} y'_0 + \frac{(2h)^3}{6!} y''_0 + \frac{(2h)^4}{24!} y'''_0 \\ + \frac{(2h)^5}{120} y^{\text{iv}}_0$$

Approximate value in $[x_0, x_2]$

$$\approx \frac{h}{3} [y_0 + 4y_1 + y_2]$$

$$\approx \frac{h}{3} \left[y_0 + 4 \left(y_0 + hy'_0 + \frac{h^2}{2!} y''_0 + \dots \right) \right]$$

$$+ \left(y_0 + 2hy'_0 + \frac{(2h)^2}{2!} y''_0 + \dots \right] \right]$$

Error in $[x_0, x_2] = x - x_A$

$$= h^5 \left(\frac{32}{120} - \frac{5}{18} \right) y^{\text{iv}}_0$$

$$= -\frac{h^5}{90} y^{\text{iv}}_0$$

$$\text{Total error } E = -\frac{h^5}{90} [y^{\text{iv}}_0 + y^{\text{iv}}_2 + \dots + y^{\text{iv}}_{n-2}] \\ \underbrace{\qquad\qquad\qquad}_{n/2 \text{ terms}}$$

$$= -\frac{h^5}{90} \times \left(\frac{n}{2} \right) \tilde{y}^{\text{iv}}$$

$$= -\frac{(b-a)}{90} h^4 \tilde{y}^{\text{iv}}$$

$$\text{Where } \tilde{y}^{iv} = \frac{y_0^{iv} + \dots + y_{n-2}^{iv}}{n/2}$$

which is the mean value of the 4th derivative at starting point of subintervals.

(4) Simpsons (3/8)th rule

In this method of approximating integral we take four tabulated points in each subintegral,

$$\text{Hence } \int_{x_0}^{x_n} y dx \approx \int_{x_0}^{x_3} y dx + \int_{x_3}^{x_6} y dx + \dots + \int_{x_{n-3}}^{x_n} y dx$$

And it is approximated by,

$$\int_{x_0}^{x_n} y dx \approx h \left[y_0 + 3y_1 + 3y_2 + y_3 + \dots + y_{n-1} \right]$$

$$\therefore \int_{x_0}^{x_n} y dx \approx \frac{3h}{8} [y_0 + 3y_1 + 3y_2 + y_3]$$

$$+ \frac{3h}{8} [y_3 + 3y_4 + 3y_5 + y_6]$$

$$+ \frac{3h}{8} [y_{n-3} + 3y_{n-2} + 3y_{n-1} + y_n]$$

$$\approx \frac{3h}{8} [y_0 + 2(y_1 + y_2 + y_3 + \dots + y_{n-2} + y_{n-1})]$$

$$+ 2(y_3 + y_6 + \dots + y_{n-3}) + y_n]$$

Note

Simpsons $(3/8)^{\text{th}}$ rule is applicable if tabulated points are of the form $M(3)+1$
i.e. $4, 7, 10, 13, \dots$

In the actual curve for approximation of integral by simpsons $(3/8)^{\text{th}}$ rule is of order upto 3 then approximate value and the value of the integral will coincide.

Q. By simpsons $(3/8)^{\text{th}}$ rule approximate value of integral $\int_0^{10} (x^3 + x^2 - x + 1) dx$ by taking step length $(1/10)$ will be — ?

$$\Rightarrow 1) \frac{10^4}{4} + \frac{10^3}{3} + \frac{10^2}{2} + 10$$

$$2) 10$$

$$3) 0$$

$$4) \text{None}$$

As set of points by step length $1/10$ are

$$0, 1/10, 2/10, 3/10, \dots, 100/10$$

101 points

$$101 \neq M(3) + 1$$

$$\text{as } 101 = 99 + 2$$

$$= M(3) + 2 \neq M(3) + 1$$

\therefore This formula not applicable

Ans : (4)

Q. $\int_0^3 (x^3 + x^2 - x + 1) dx$, step length $10/6$

$$\Rightarrow 0 \quad 10/6 \quad 20/6 \quad 30/6 \quad 40/6 \quad 50/6 \quad 60/6$$

7 points

$$f = 6 + 1$$

$$= f(3) + 1$$

\therefore formula ii applicable and the value is Ans. : (1) above

Error

Actual value (x):

$$x = \int_{x_0}^{x_3} y dx = \int_{x_0}^{x_3} y_0 + (x-x_0) y'_0 + \frac{(x-x_0)^2}{2!} y''_0 + \dots$$

$$= 3h y_0 + \frac{(3h)^2}{2!} y'_0 + \frac{(3h)^3}{3!} y''_0 + \dots$$

Approximate value in $[x_0, x_3]$

$$x_A \approx \int_{x_0}^{x_3} y dx = \frac{3h}{8} [y_0 + 3y_1 + 3y_2 + y_3]$$

x_A in $[x_0, x_n]$ if

$$\int_{x_0}^{x_n} y dx = \frac{3h}{8} [y_0 + 3y_1 + 3y_2 + y_3]$$

$$+ \frac{3h}{8} [y_3 + 3y_4 + 3y_5 + y_6]$$

$$\approx \frac{3h}{8} [y_{n-3} + 3y_{n-2} + 3y_{n-1} + y_n]$$

$$\approx \frac{3h}{8} [y_0 + 3(y_1 + y_2 + \dots + y_{n-1}) + 2(y_n + y_{n-1} + \dots + y_{n-3}) + y_n]$$

- Numerical Sol's of ODE -

If we have function of two variables x, y
then $f(x+h, y+k) = f(x, y) + h \frac{\partial f}{\partial x} + k \frac{\partial f}{\partial y}$

$$+ h^2 \frac{\partial^2 f}{\partial x^2} + k^2 \frac{\partial^2 f}{\partial y^2} + 2hk \frac{\partial^2 f}{\partial x \partial y} + \dots$$

is known as Taylors expansion of $f(x, y)$.

In this topic we will be given $y' = f(x, y)$
and initial condition $y(x_0) = y_0$, i.e. $y(x_0) = y_0$.

In this topic we have two goals:

- 1) Evaluate $y(x)$.
- 2) Evaluate $y(x_i) = y_i$,

→ 1) Taylors method (Not in syllabus).

→ 2) Picards method (In syllabus).

→ 3) Eulers method.

→ 4) Improved Euler.

→ 5) Modified Euler.

→ 6) Runge kutta method.

1) Taylors Method: (Not in syllabus)

$$y(x) = y_0 + (x - x_0) y'_0 + \frac{(x - x_0)^2}{2!} y''_0 + \dots$$

$$y(0) = y_0$$

$$y'_0 = f(x_0, y_0)$$

$$y''_0 = f_x(x_0, y_0, y'_0)$$

$$y'''_0 = f_{xx}(x_0, y_0, y'_0)$$

$$y^n_0 = F_{n-1}(x_0, y_0, y'_0, y''_0, \dots, y^{n-1}_0)$$

2) Picard's Method

$$y' = \frac{dy}{dx} = f(x, y) \text{ --- given}$$

$$dy = f(x, y) dx$$

$$\int_{x_0}^x dy = \int_{x_0}^x f(x, y) dx$$

$$\Rightarrow y(x) - y(x_0) = \int_{x_0}^x f(x, y) dx$$

$$y - y_0 = \int_{x_0}^x f(x, y) dx$$

$$\therefore y = y_0 + \int_{x_0}^x f(x, y) dx$$

1st approximation:

$$y^{(1)} = y_0 + \int_{x_0}^x f(x, y) dx$$

$$y^{(2)} = y_0 + \int_{x_0}^x f(x, y^{(1)}) dx$$

proceeding in this manner,

$$y^{(n)} = y_0 + \int_{x_0}^x f(x, y^{n-1}) dx$$

$n=1, 2, \dots, y^{(0)} = y_0$

Q. Consider $y' = x + y$. and $y(0) = 1$

find y as a function of x

1) By Taylor's method upto 3rd power n

2) By Picard's method upto 2nd iteration.

$$\Rightarrow y' = x + y, \quad y'(0) = y(0) = 1$$

$$y'' = y' + y', \quad y''(0) = 1 + y'(0) = 2$$

$$y''' = y'' \quad y'''(0) = 2$$

$$y = 1 + (x - x_0) + \frac{(x - x_0)^2}{2!} (2) + \frac{(x - x_0)^3}{3!} (2)$$

$$= 1 + (x - 0) + \frac{(x - 0)^2}{2!} (2) + \frac{(x - 0)^3}{3!} (2)$$

$$= 1 + x + \frac{x^2}{3} + \frac{x^3}{3}$$

By picards method:

$$y^{(1)} = 1 + \int_0^x f(x, y) dx$$

$$= 1 + \int_0^x (x+1) dx$$

$$= 1 + \frac{x^2}{2} + x$$

$$y^{(2)} = 1 + \int_0^x \left(\frac{x^2}{2} + x + 1 \right) dx$$

$$= 1 + \frac{x^3}{6} + \frac{x^2}{2} + x$$

~~.....~~

3. Eulers Method.

To find values of y at certain points

$$\begin{aligned} y' &= f(x, y) \\ y(x_0) &= y_0 \end{aligned} \quad \left. \begin{array}{l} \\ \text{given} \end{array} \right\}$$

$$y(x_1) = ?$$

$$\int_{x_0}^{x_1} dy = \int_{x_0}^{x_1} f(x, y) dx$$

$$y_1 - y_0 = \int_{x_0}^{x_1} f(x, y) dx$$

$$y_1 = y_0 + \int_{x_0}^{x_1} f(x, y) dx$$

(Q) Co

In Eulers method to find approximate value of $y(x)$

$$\text{let } f(x, y) = f(x_0, y_0) \text{ in } [x_0, x_1]$$

$$y_1 \approx y_0 + h f(x_0, y_0)$$

4. Improved Eulers method. (Explicit trapezoidal)

Instead of approximating the value of $f(x, y)$ at initial point $f(x_0, y)$ was taken as mean of the value at the two end points.

$$f(x, y) = \frac{f(x_0, y_0) + f(x_1, \tilde{y}_1)}{2}$$

$$\text{where } \tilde{y}_1 = y_0 + h f(x_0, y_0) \dots \text{by Euler above}$$

$$y_1 \approx y_0 + \frac{h}{2} [f(x_0, y_0) + f(x_1, \tilde{y}_1)]$$

5. Modified Eulers Method.

In this method n^{th} approximation at y_1 was taken as by trapezoidal rule

$$y_1^{(n)} = y_0 + \int_{x_0}^{x_1} \left(\frac{f(x_0, y_0) + f(x_1, y_1^{n-1})}{2} \right) dx$$

$$y_1^{(n)} = y_0 + \frac{h}{2} [f(x_0, y_0) + f(x_1, y_1^{n-1})] \quad n=1, 2, 3, \dots$$

$$y_1^{(0)} = y_0 + h f(x_0, y_0).$$

(Q)

Consider differential equation.

$y' = x+y$ subject to the condition

$y(0) = 1$ find value of $y(0.1)$ by taking step length 0.1 .

1) By Eulers method.

2) By Improve Euler method.

3) Modified Euler.

$$\Rightarrow f(x, y) = x+y$$

$$f(x_0, y_0) = 0+1 = 1$$

$$h = 0.1$$

$$\begin{aligned} 1) \quad y(0.1) &= y(0) + h f(x_0, y_0) \\ &= 1 + (0.1) \cdot 1 \\ &= 1.1 \end{aligned}$$

$$2) \quad y(0.1) = y(0) + \frac{h}{2} [f(x_0, y_0) + f(x_0, \tilde{y}_1)]$$

$$h = 0.1, \quad \tilde{y}_1 = 1.1$$

$$f(x_1, \tilde{y}_1) = 0.1 + 1.1 \\ = 1.2$$

$$\therefore y(0.1) = 1 + \frac{0.1}{2} [1 + 1.2] \\ = 1.11$$

$$(3) \quad y_1^{(n)} = y_0 + \frac{h}{2} [f(x_0, y_0) + f(x_1, y_1^{n-1})]$$

$$y_1^{(n)} = 1 + \frac{0.1}{2} [1 + 0.1] + y_1^{n-1} \\ = 1 + 0.05 [1.1 + y_1^{n-1}]$$

$$y_1^{(0)} = 1.1 \text{ by Euler's method.}$$

$$\therefore y_1^{(1)} = 1 + 0.05 [1.1 + 1.1] \\ = 1 + 0.05 (2.2) \\ = 1.11$$

$$y_1^{(2)} = 1 + 0.05 [1.11 + 1.11] \\ = 1.1105$$

Now compare all the three approximate value with the actual value.

Actual sol? of

$$(D-1) y = x \quad y' = x + y$$

$$\text{is } y(x) = 2e^x - (n+1)$$

$$y(0.1) = 2 e^{0.1} - (1.1)$$

Error in Eulers method.

$$E = 2e^{0.1} - 1.1 - 1.1 \\ = 2e^{0.1} - 2.2$$

6. Runge-Kutta method. (R-K method)

In this method of finding approximate value of y_1 , Error were taken into consideration and according to which different-order R-K methods were developed.

If we have R-K method of order k then error will be of the order h^{k+1} .

The superbit R-K method is R-K method of order 3 that means error will be of order 3.

R-K method of order 2 is given by

$$y_1 = y_0 + k_1, k_1 + k_2, k_2$$

$$\text{where } k_1 = h f(x_0, y_0) = h f_0$$

$$k_2 = h f(x_0 + \alpha h, y_0 + \beta k_1)$$

$$\text{As } y' = f(x, y), y(0) = y_0$$

$$\frac{df}{dx} = \frac{\partial f}{\partial x} + f \frac{\partial f}{\partial y} \cdot \frac{dy}{dx} \\ = \frac{\partial f}{\partial x} + f \frac{\partial f}{\partial y}$$

$$y_0 + k_1 (h f_0) + k_2 [h f(x_0, y_0) + \alpha h \frac{\partial f}{\partial x} \\ + \beta h f_0 \frac{\partial f}{\partial y}]$$

$$hf_0 \quad w_1 + w_2 = 1 \quad \Rightarrow$$

$$\frac{h^2}{2} \frac{\partial f}{\partial x} \quad w_2 \alpha = \frac{1}{2}$$

$$\frac{h^2}{2} \frac{\partial f}{\partial y} \quad w_2 \beta = \frac{1}{2}$$

$$\alpha = \beta = 1$$

$$\Rightarrow w_1 = \frac{1}{2}, \quad w_2 = \frac{1}{2}$$

$$\text{and } k_1 = hf_0$$

$$k_2 = hf(x_0 + h, y_0 + k_1)$$

$$\therefore y_1 = y_0 + \frac{1}{2} (k_1 + k_2)$$

$$y_1 = y_0 + \frac{1}{2} (k_1 + k_2)$$

$$k_1 = hf(x_0, y_0)$$

$$k_2 = hf(x_0 + h, y_0 + k_1)$$

~~for~~

Q. By Range-Kutta method

find 1) k_1

2) k_2

3) $y(0.1)$

for initial value problem

$$y' = x + y, \quad y(0) = 1$$

$$\Rightarrow k_1 = hf(x_0, y_0) \\ = (0.1) \times [0+1] \\ = 0.1$$

$$k_2 = hf(x_0 + h, y_0 + k_1) \\ = 0.1 (0.1 + 1.1) \\ = 0.12$$

$$y(0.1) = 1 + \frac{h}{2} (0.1 + 0.12) \\ = 1.11$$
